

A Randomized Quick Sort

Assume that elements of A are distinct.

Instead of choosing $A[r]$ as the Pivot,

We will select a randomly chosen element from the array $A[p..r]$ as a Pivot.

Now, we expect the split of the input array to be reasonably well balanced on average.

RANDOMIZED-PARTITION(A, p, r)

- 1 $i = \text{RANDOM}(p, r)$ \rightarrow Chooses an index b/w p & r uniformly random and independently.
- 2 exchange $A[r]$ with $A[i]$
- 3 **return** PARTITION(A, p, r)

RANDOMIZED-QUICKSORT(A, p, r)

- 1 **if** $p < r$
- 2 $q = \text{RANDOMIZED-PARTITION}(A, p, r)$
- 3 RANDOMIZED-QUICKSORT($A, p, q - 1$)
- 4 RANDOMIZED-QUICKSORT($A, q + 1, r$)

PARTITION(A, p, r)

1 $x = A[r]$

2 $i = p - 1$

3 **for** $j = p$ **to** $r - 1$

4 **if** $A[j] \leq x$

5 $i = i + 1$

6 exchange $A[i]$ with $A[j]$

7 exchange $A[i + 1]$ with $A[r]$

8 **return** $i + 1$

Q: How many times PARTITION Subroutine is called

in the entire execution of the quick sort algorithm.

A: at most n calls

One call to Partition takes $O(1)$ time +
amount of time that is proportional to the number
of iterations of the for loop (lines 3-6)

Since each iteration of the for loop performs
a comparison in line 4, comparing the pivot element
to another element of the array A.

Therefore, ^{if} we count the total # of times line 4
is executed, we can bound the total time spent
in the for loop during the entire execution of
QUICKSORT.

Let X be the total number of comparisons performed in all calls to PARTITION.

Then total time $O(n + X)$

↓
at most n calls to the PARTITION, each of which const amount of work.

Goal: To compute X .

Idea: Instead of finding # of comparisons in each call to PARTITION, we can find an overall bound on the total number of comparisons.

We rename the elements of the array ~~are~~ as

$$z_1, z_2, \dots, z_n$$

where z_i is the i^{th} smallest element of A

Ex: $A = [4, 6, 2, 3]$

then $z_1 = 2, z_2 = 3, z_3 = 4, z_4 = 6$

let $Z_{ij} = \{z_i, z_{i+1}, \dots, z_j\}$ be the set of elements b/w z_i and z_j , inclusive.

z_i and z_j

Q1 Fix two elements of ip array. How many times

can these two elements be compared during the execution of Quicksort?

Q2 When does the algorithm compare z_i and z_j

$$\text{Let } X_{ij} = \begin{cases} 1 & \text{if } z_i \text{ is compared to } z_j \\ 0 & \text{o.w} \end{cases}$$

Here too, we are considering whether the comparison takes place at any time during the execution of the algorithm, not just ~~one~~ during one call of PARTITION.

From Q1 above, each pair is compared at most once, we get

$$X = \sum_{i=1}^{n-1} \sum_{j=i+1}^n X_{ij}$$

$$\begin{aligned} E[X] &= E\left[\sum_{i=1}^{n-1} \sum_{j=i+1}^n X_{ij}\right] \\ &= \sum_{i=1}^{n-1} \sum_{j=i+1}^n E[X_{ij}] \end{aligned}$$

$$= \sum_{i=1}^{n-1} \sum_{j=i+1}^n \Pr[z_i \text{ is compared to } z_j]$$

now, we will compute this quantity.

$z_1 \dots z_i z_{i+1} \dots z_j z_{j+1} \dots z_n$

If a pivot x is chosen such that $z_i < x < z_j$

then z_i and z_j cannot be compared at any subsequent time.

If z_i is chosen as a pivot before any other element in Z_{ij} , then z_i will be compared with each element of Z_{ij} , except itself.

Similarly if z_j is chosen as a pivot before any other element in Z_{ij} , then z_j will be compared with each element of Z_{ij} , except itself.

$$\Pr[Z_i \text{ is compared with } z_j]$$

$$= \Pr[Z_i \text{ or } z_j \text{ is first Pivot chosen from } Z_{ij}]$$

$$= \Pr[Z_i \text{ is first Pivot chosen from } Z_{ij}] + \\ \Pr[z_j \text{ is first Pivot chosen from } Z_{ij}]$$

$$= \frac{1}{j-i+1} + \frac{1}{j-i+1}$$

$$= \frac{2}{j-i+1}$$

$$\therefore E[X] = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \frac{2}{j-i+1}$$

let $k = j - i$ then

$$E[X] = \sum_{i=1}^{n-1} \sum_{k=1}^{n-i} \frac{2}{k+1}$$

$$< \sum_{i=1}^{n-1} \sum_{k=1}^n \frac{2}{k}$$

$$= \sum_{i=1}^{n-1} O(\log n)$$

$$= O(n \log n)$$

\therefore The expected running time of Randomized Quicksort is $O(n \log n)$ if the elements are distinct.
