

## Divide and Conquer Paradigm

### [Recap]

- ① Divide into smaller subproblems
- ② Conquer via recursive calls
- ③ Combine solutions of subproblems.

## The Maximum Subarray Problem

[Reference:  
Cormen book]  
Section 4.1

Given the daily stock prices of some company.

You are allowed to buy one unit of stock only one time and then sell it at a later date.

Our goal is to maximize the profit.

### Example ①

Day	0	1	2	3	4
Price	10	11	7	10	6

Sol: Buy after day-2 and sell after day 3

$$\text{Profit} = 10 - 7 = 3.$$

### Brute-force solution:

Try every possible pair of buy and sell dates in which the buy date precedes the sell date.

Total we have  $\binom{n}{2}$  pairs, that is, we have to spend  $\Omega(n^2)$  time.

Q: Can we do better? ie, Algorithm with running time  $O(n^2)$ .

### Previous example

Day	0	1	2	3	4	5	6	7	8
Price	10	11	7	10	4	9	8	6	12
change	-	1	-4	3	-6	5	-1	-2	6

Instead of looking at the daily prices, we look at the daily change in price, where the change on day  $i$  is the difference between the prices after day  $i-1$  and after day  $i$ .

We use  $A$  to denote the change array

"Then the Problem reduces to find a non-empty, contiguous subarray of A whose sum of values is maximum" — Maximum Subarray Problem.

Observe that if the array A contains only nonnegative entries, then the problem is easy, the entire array would give the greatest sum.

### Brute-force Solution

MAXIMUM-SUBARRAY (A, low, high)

- 1             $\text{maxSum} = -\infty$
- 2            For  $i = \text{low}$  to  $\text{high}$
- 3                  $\text{currSum} = 0$
- 4                 For  $j = i$  to  $\text{high}$
- 5                          $\text{currSum} = \text{currSum} + A[j]$
- 6                                 if  $\text{currSum} > \text{maxSum}$
- 7                                          $\text{maxSum} = \text{currSum}$

Time Complexity =  $O(n^2)$

where  $n$  is the number of elements in A.

## A solution using Divide-and-Conquer

We want to find a maximum subarray of the array  $A[\text{low}, \dots, \text{high}]$ .

We divide the array into two subarrays of as equal size as possible.

Let  $\text{mid}$  denotes the midpoint of the array, we consider two subarrays  $A[\text{low} \dots \text{mid}]$  and  $A[\text{mid}+1, \dots, \text{high}]$

Then any contiguous subarray  $A[i \dots j]$  of  $A[\text{low}, \dots, \text{high}]$  must lie in exactly one of the following places.

- ① Entirely in  $A[\text{low} \dots \text{mid}]$ , that is  $\text{low} \leq i \leq j \leq \text{mid}$
- ② Entirely in  $A[\text{mid}+1, \dots, \text{high}]$ , that is  $\text{mid} < i \leq j \leq \text{high}$
- ③ Crossing the midpoint, that is  $\text{low} \leq i \leq \text{mid} < j \leq \text{high}$

Therefore, a maximum subarray of  $A[\text{low} \dots \text{high}]$  must lie in exactly one of these places.

We can find maximum subarrays of  $A[\text{low} \dots \text{mid}]$  and  $A[\text{mid} + 1 \dots \text{high}]$  recursively.

So we only have to find a maximum subarray that crosses the midpoint, then we take a subarray with largest sum of the three.

We now describe a linear time algorithm to find maximum subarray crossing the midpoint.

(Note that this is NOT a smaller instance of our original problem)

FIND-MAX-CROSSING-SUBARRAY( $A, low, mid, high$ )

```
1 left-sum =  $-\infty$ 
2 sum = 0
3 for  $i = mid$  downto  $low$ 
4     sum = sum +  $A[i]$ 
5     if sum > left-sum
6         left-sum = sum
7         max-left =  $i$ 
8 right-sum =  $-\infty$ 
9 sum = 0
10 for  $j = mid + 1$  to  $high$ 
11     sum = sum +  $A[j]$ 
12     if sum > right-sum
13         right-sum = sum
14         max-right =  $j$ 
15 return (max-left, max-right, left-sum + right-sum)
```

Total number of iterations  $(mid - low + 1) + (high - mid)$   
 $= n$  ( $n$ : size of  $A$ )

$\therefore$  FIND-MAX-CROSSING-SUBARRAY( $A, low, mid, high$ )

takes  $\Theta(n)$  time.

Next we describe a divide and Conquer algorithm  
to solve the maximum Subarray Problem.

FIND-MAXIMUM-SUBARRAY( $A, low, high$ )

```
1  if high == low
2      return (low, high, A[low])           // base case: only one element
3  else mid =  $\lfloor (low + high)/2 \rfloor$ 
4      (left-low, left-high, left-sum) =
        FIND-MAXIMUM-SUBARRAY( $A, low, mid$ )
5      (right-low, right-high, right-sum) =
        FIND-MAXIMUM-SUBARRAY( $A, mid + 1, high$ )
6      (cross-low, cross-high, cross-sum) =
        FIND-MAX-CROSSING-SUBARRAY( $A, low, mid, high$ )
7      if left-sum  $\geq$  right-sum and left-sum  $\geq$  cross-sum
8          return (left-low, left-high, left-sum)
9      elseif right-sum  $\geq$  left-sum and right-sum  $\geq$  cross-sum
10         return (right-low, right-high, right-sum)
11     else return (cross-low, cross-high, cross-sum)
```

Running time analysis:

$T(n)$  : denote the running time of

FIND-MAXIMUM-SUBARRAY( $A, low, high$ ) on a subarray of  $n$ -elements.

If  $n=1$  (base case) ;  $T(1) = 1 = \Theta(1)$

We get the following recurrence

$$T(n) = \begin{cases} 2T(n/2) + \Theta(n) & \text{if } n > 1 \\ 1 & \text{if } n = 1 \end{cases}$$

$\therefore T(n) = \Theta(n \log n)$  [asymptotically faster than Brute-force]

In Dynamic Programming topic, we study Kadane's algorithm having  $O(n)$  runtime, for maximum-subarray problem.
