# Basic Definitions

A graph G is a Pair of Sets (V, E),

Where V is an arbitrary non-empty set and

E is a Set of Pairs of elements of V.

Elements of V and E are called Vertices (nodes)

and edges (links) of G1 Respectively.

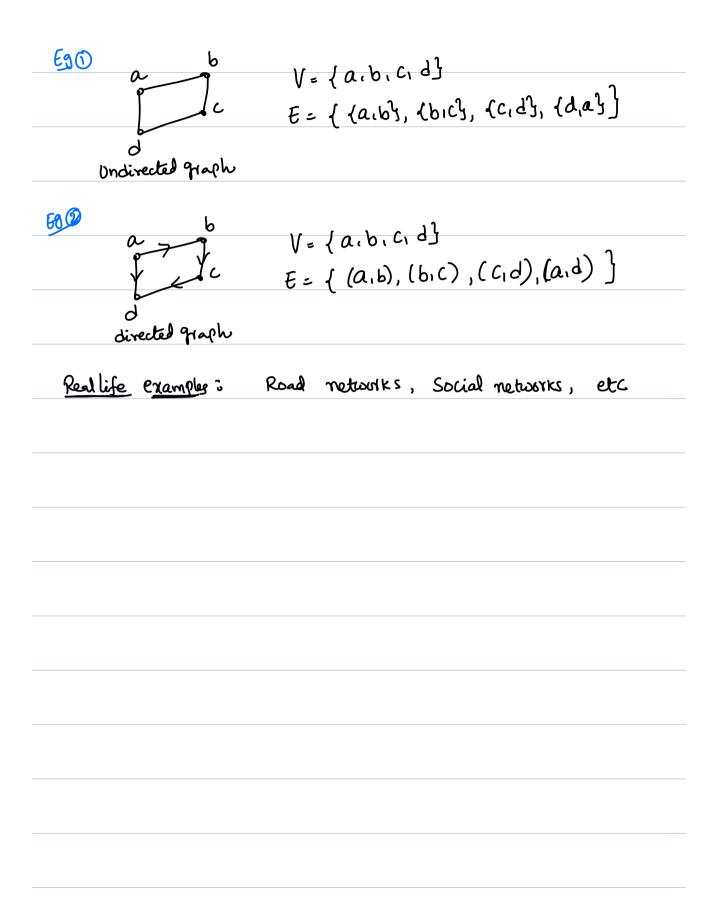

In an undirected graph, the edges are unordered Pairs (sets of size two). We use use us instead of {u.u} to denote the undirected edge between vertices u and v.

In a directed graph, the edges are ordered

In a directed graph, the edges are ordered Pairs of Vertices. We use (U,V) denote the directed edge from U to U.

Us ually M - denotes # of Vertices.

m - 11 11 edges.

let G=(V, E) be an undirected graph.

Path: A path P is a Sequence of distinct Vectices

1, 1/2, -- 1/2 such that each Consecutive Pair

Vi, Viti is joined by an edge in G.

P is Called a Path from 1/1 to 1/2.

Cycle: A cycle is a Path  $v_1, v_2 - v_k$ , (k>2)With  $v_1 = v_k$ .

Connected: An undirected graph is Connected it for every Pair of modes u and v there is a Path from u to v.

Tree: An undirected graph is a tree if it is

Connected and does not Contain a Cycle.

Subgraph: A Subgraph of a graph G is another
graph formed from a Subset of the vertiles and
edges of G.
b a b
Example: a
G H
His a Subgraph of G.
Exercise
hove that  (1) Every tree on n Vertices has exactly n-1 edges

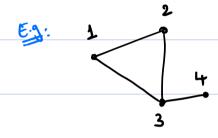

Other Terminology
@ degree
3 Subgraph, indued Subgraph
4) Walk, Path, Cycle, length of the Path Cycle
6 Connected graph, Components, Strongly Connected
6 Tree, Forest, DAG
a distance in the graphs (weighted us unweighted)

# Representation of Graphs

There are several ways to represent graphs,
each with its advantages and disadvantages.
In this course we will see three ways to
defresent graphs.
① Edge lists
2 Adjacency matrices
3 Adjacency Lists

Edge list

An edge list is a list or array of all the edges of the graph.

Total space for an edge list is O(E)

<u>disadvantage</u>:

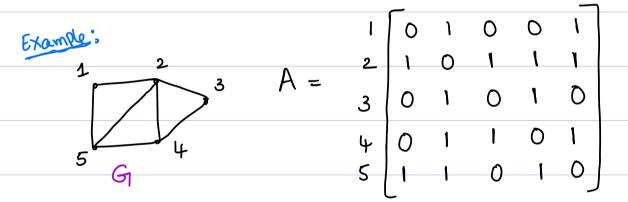

It we want to find whether the graph contains a particular edge, we have to search through the edge list, In the worst case we have to search through | El edges.

## Adjacency matrices

in some arbitrary manner.

The adjacency matrix of a graph G is a  $V \times V$  matrix  $A = (a_{ij})$  of 0's and 1's such that

$$a_{ij} = \begin{cases} 1 & \text{if } ij \in E \\ 0 & \text{otherwise} \end{cases}$$

Adjacency matrix representation of G.

Remark: For an undirected graph, the adjacency

matrix is Symmetric.

for a directed graph the adjacency matrix

need not be symmetric.

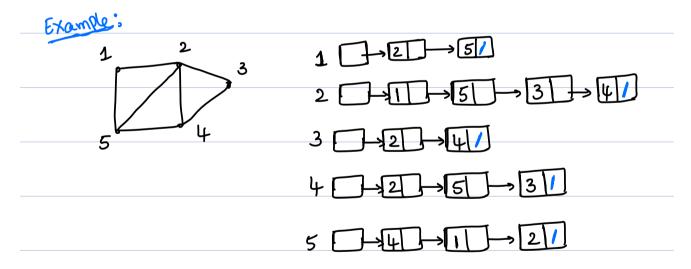

We can find out whether an edge is Present in constant time by just booking up the Corresponding entry in the matrix

#### <u>disadvantage</u>:

- O Adjacency matrix representation of a graph  $Sequires \Theta(n^2)$  Space, irrespective of the # of edges in the graph.
- Diven vertex i, we have to look at all lentries in row i, even it only a small number of vertices are adjacent to a vertex i

## Adjacency Lists:

An adjacency list is an array of lists, each containing the neighbors of one of the Vertices (out-neighbors it the graph is directed).

This representation uses an array indexed by vector number, in which the array cell for each vector Points to a Singly linked list of the neighboring vectices.

- The Overall Space required for an adjacency

  List is O(n+m) { Some books write O(V+E)}

  #4 Vector #4 edges O(|V|+|E|)
- (2) The Standard way to implement the adjacency list is using a array (list) of Single-linked lists, where the head of the linked list is the Vertex and all the Connected linked lists are the Vertices to which it is Connected.
- 3 we can find neighbors of a vertex i in  $\Theta(\frac{d_i}{d_i})$  time, where di is the degree of vertex i.

Companison:

	Adjacency list	Adjacency matrix
O Space	O (V+E)	$\theta(v^2)$
10 Test if UVEE	(1+min (deg (W), deg (W)))	0(1)
3 Test it (U.V) EE	0(1+ deg (w) =0(V)	٥(۱)
4 List v's (out)-neigh		OLV)
6 list all edges	O (V+E)	$\Theta(v^2)$
6 Insert edge UU	<mark>O(I</mark> )	0(1)
3 Delete edge UV	0( deg(W)+deg(W)) = O(1	) O(1)
1 Adding a Veeter	0(1)	(Shorage Stace
(a) And dine can a day	0(1)	number in creased. $O(1)$
1 Adding on edge  1 Delete a veeter	O(V+E)	<mark>0(                                    </mark>

Relation Ship blus nam: urdirected & G is Connected & without Parallel edges & Selt loops If  $\eta - 1 \leq m \leq {\eta \choose 2}$ then Sparse us Dense Gnaphs In most applications m is 12(11) and 0(12) (Roughly) graph m is O(n) or close to it In a Spanse In a dense graph m is close to O(m2)

# Adjacency Lists ( We use this sepresentation in this course)

if a graph is Sparse, then most of entries in adjacency matrix are zero (which is a waste of space). Hence, we generally use adjacency list representation for sparse graphs.

\* It G has n Vertices & m edges then

Adjacency list representation requires  $\Theta$  (mtn) Space.
